

# BRAVE INDUCTION

**CHIAKI SAKAMA**

Wakayama University

**KATSUMI INOUE**

National Institute of Informatics

*ILP 2008, Prague*

# Background

- Typical ILP tasks construct hypotheses to explain observations using background knowledge.
- Given the background knowledge  $B$  and an observation  $O$ , a hypothesis  $H$  covers  $O$  under  $B$  if
  - $B \wedge H \models O$
  - $B \wedge H$  is consistent.
- The condition is often **too strong** for building possible hypotheses.

# Motivating Example

- There are 30 students in a class, of which 20 are European, 7 are Asian, and 3 are American.

B:  $student(1) \wedge \dots \wedge student(30)$ ,

O:  $euro(1) \wedge \dots \wedge euro(20) \wedge asia(21) \wedge \dots \wedge asia(27) \wedge usa(28) \wedge \dots \wedge usa(30)$

- In this situation, the clause  
H:  $euro(x) \vee asia(x) \vee usa(x) \leftarrow student(x)$   
appears a good candidate of hypothesis.
- However, H does not satisfy the relation  $B \wedge H \models O$ .  
In fact,  $B \wedge H$  has many models in which O is not true,  
e.g.,  $\{student(1), \dots, student(30), euro(1), \dots, euro(30)\}$ .

# What is the Problem?

- When  $B$  and  $H$  are Horn theories, the relation  $B \wedge H \models O$  (\*) represents that  $O$  is true in the unique minimal model of  $B \wedge H$ .
- When  $B \wedge H$  contains **indefinite** information,  $B \wedge H$  becomes a **non-Horn** theory which has **multiple minimal models** in general.
- In this case, the relation (\*) excludes a possible hypothesis  $H$  due to the existence of a single minimal model of  $B \wedge H$  in which  $O$  is not true.

# Contribution

- To cope with the problem, we introduce a new form of induction called **brave induction**.
- We investigate formal properties and develop an algorithm of brave induction.
- The framework is extended to induction in **answer set programming**.  
(This part is not included in this talk.)

# Brave Reasoning vs. Cautious Reasoning

- Brave (or credulous) reasoning and cautious (or skeptical) reasoning are used in nonmonotonic logics and disjunctive logic programs.
- A formula  $F$  is a consequence of brave/cautious inference in a theory  $T$  (under the minimal model semantics) if  $F$  is true in some/every minimal model of  $T$ .
- Brave/cautious reasoning is used in hypothetical reasoning in AI such as abduction.

# Brave/Cautious Abduction

- B:  $\text{light\_off} \leftarrow \text{power\_failure},$   
 $\text{light\_off} \leftarrow \text{broken\_bulb},$   
 $\text{broken\_bulb} \vee \text{melted\_fuse} \leftarrow \text{high\_current},$   
Abducible:  $\text{power\_failure}, \text{high\_current}.$
- O:  $\text{light\_off}$
- $E1 = \text{power\_failure}$  is the unique (minimal) explanation in cautious abduction, since O is true in every minimal model of  $B \wedge E1$ .
- In addition to E1,  $E2 = \text{high\_current}$  is also a (minimal) explanation in brave abduction, since O is true in some minimal model of  $B \wedge E2$ .

# Brave Induction in Clausal Logic

- B, O, and H are all consistent clausal theories.
- A hypothesis H **covers** O under B in **brave induction** if a consistent theory  $B \wedge H$  has a minimal model satisfying O. In this case, H is called a **solution** of brave induction.
- In this sense, explanatory induction in ILP is considered **cautious induction**.

# Properties (1)

- **Existence of solutions:** Brave induction has a solution iff  $B \wedge O$  is consistent.
- **Relation to cautious induction:** If  $H$  covers  $O$  under  $B$  in cautious induction,  $H$  is a solution of brave induction. The converse holds when  $B$  is a Horn theory.
- **Necessary condition of solutions:** If  $H$  is a solution of brave induction,  $B \wedge H \wedge O$  is consistent.

## Properties (2)

- **Generalization of solutions:** For any theory  $H' \models H$  such that  $B \wedge H'$  is consistent, if  $H$  is a solution of brave induction, so does  $H'$ .
- **Nonmonotonicity:** The fact that  $H1$  and  $H2$  are solutions of brave induction does not imply that  $H1 \wedge H2$  is a solution.
- **Disjunctive combination of solutions:** If  $H1$  and  $H2$  are solutions of brave induction, so is  $H1 \vee H2$ .

## Properties (3)

- **Conjunctive combination of observations:**  
The fact that  $H$  covers both  $O1$  and  $O2$  under  $B$  does not imply  $H$  covers  $O1 \wedge O2$  under  $B$ .
- Ex) Let  $B = \{ p(x) \vee q(x) \leftarrow r(x), s(a) \leftarrow \}$ ,  
 $O1 = \{ p(a) \}$ , and  $O2 = \{ q(a) \}$ .  
Then,  $H = \{ r(x) \leftarrow s(x) \}$  covers both  $O1$  and  $O2$  under  $B$  in brave induction, but  $H$  does not cover  $O1 \wedge O2$  under  $B$ .  
Note that  $B \wedge H$  has two minimal models  $\{ p(a), r(a), s(a) \}$  and  $\{ q(a), r(a), s(a) \}$ .

# Comparison of Properties

	Brave ind.	Cautious ind.
Generalization of solutions	●	●

Disjunctive combination of solutions	●	●
Conjunctive combination of observations	×	●

# Computation

- **Proposition:**

B: background knowledge,

H: a hypothesis,

O: an observation.

$B \wedge H$  has a minimal model satisfying O  
iff there is a disjunction F of ground atoms s.t.

$$B \wedge H \models O \vee F \text{ and } B \wedge H \not\models F.$$

- **Assumption:**

- O is a conjunction of ground atoms.

- H is a finite clausal theory s.t. the head of each clause has the predicate appearing in O.

# Terms and Notions

- A ground clause  $C$  is **prime** wrt  $T$  if  $T \models C$  but  $T \not\models C'$  for any  $C' \subset C$ .
- A DNF formula  $F = C_1 \vee \dots \vee C_k$  is **irredundant** if  $F \not\equiv F'$  for any  $F' = C_1 \vee \dots \vee C_{i-1} \vee C_{i+1} \vee \dots \vee C_k$ .
- Given an atom  $A$ ,  
**pred(A)** is the predicate of  $A$ ,  
**term(A)** is the set of terms in  $A$ ,  
**const(A)** is the set of constants in  $A$ .
- Given a clause  $C$ , **head(C)** is the head of  $C$ ,  
and **body(C)** is the body of  $C$ .

# Step 1: Computing ground hypotheses

- $B \wedge H \models O \vee F$  implies  $B \wedge \neg O \models \neg H \vee F$ .
- $H$  is a clausal theory and  $F$  is a disjunction of ground atoms, then  $\neg H \vee F$  is a DNF formula.
- To get  $\neg H \vee F$ , first compute prime CNF formulas from  $B \wedge \neg O$ . Then, construct an irredundant DNF formula from it.
- From  $\neg H \vee F$ , extract  $\neg H$ .
- By  $\neg H$ , we can obtain  $H$ .

## Step 2: Generalization

- $O$  is partitioned into disjoint subsets

$$O = O_1 \wedge \dots \wedge O_n$$

where  $O_i$  is a conjunction of ground atoms having the same predicate.

- Correspondingly,  $H$  is partitioned as

$$H = H_1 \wedge \dots \wedge H_n$$

where  $H_i$  is a conjunction of clauses whose heads contain the predicate in  $O_i$ .

- Compute the **least generalization under subsumption (LGS)** of each  $H_i$  and collect it as

$$\text{lgs}(H) = \text{lgs}(H_1) \wedge \dots \wedge \text{lgs}(H_n).$$

## Step 3: Construct a weak form of hypotheses

- Given a set  $S$  of atoms, suppose two atoms  $A1$  and  $A2$  in  $S$  s.t.  $\text{pred}(A1) \neq \text{pred}(A2)$ . Then,  $\text{pred}(A1)$  and  $\text{pred}(A2)$  are **synchronous** in  $S$  if  $\text{const}(A1) \cap \text{const}(A2) \neq \emptyset$ . Otherwise, they are **asynchronous** in  $S$ .
- A set  $S$  is **asynchronous** if any pair of different predicates is asynchronous in  $S$ .
- When an observation  $O$  is an asynchronous set, take the **greatest specialization under implication (GSI)** of  $\text{lgs}(H1), \dots, \text{lgs}(Hn)$  as  $\text{gsi}(\text{lgs}(H1), \dots, \text{lgs}(Hn)) = \text{lgs}(H1) \vee \dots \vee \text{lgs}(Hn)$ .

## Step 4: Optimization

- Two atoms  $A1$  and  $A2$  are **linked** if  $\text{term}(A1) \cap \text{term}(A2) \neq \emptyset$ .
- Given a clause  $C$ , an atom  $A \in \text{body}(C)$  is **isolated** in  $C$  if there is no atom  $A' (\neq A)$  in  $C$  s.t.  $A'$  and  $A$  are linked.
- For any clause  $C$  in  $\text{lgs}(Hi)$ ,
  1. remove any atom  $A$  from  $\text{head}(C)$  s.t.  $\text{pred}(A)$  is not included in  $O$ ,
  2. remove any atom  $A$  from  $\text{body}(C)$  s.t.  $A$  is isolated in  $C$ .

The result of such reduction is denoted by  $\text{lgs}^*(Hi)$ .

# An Algorithm for Brave Induction

Procedure: BRAIN

Input: B and O;

Output: hypotheses  $H^\wedge$  and  $H^\vee$ .

Step 1: Compute ground and irredundant DNF formulas  $\neg H \vee F$  from  $B \wedge \neg O$ , and extract  $\neg H$  from  $\neg H \vee F$ .

Step 2: Compute  $\text{lgs}(H)$ .

Step 3: If O is asynchronous and is partitioned into  $O = O_1 \wedge \dots \wedge O_n$ , compute  $\text{gsi}(\text{lgs}(H_1), \dots, \text{lgs}(H_n))$ .

Step 4: If  $B \wedge \text{lgs}^*(H_i)$  is consistent, put  $H^\wedge = \text{lgs}^*(H_1) \wedge \dots \wedge \text{lgs}^*(H_n)$  and  $H^\vee = \text{lgs}^*(H_1) \vee \dots \vee \text{lgs}^*(H_n)$ .

# Main Theorem

- Any hypothesis computed by BRAIN becomes a solution of brave induction.

# Example

B:  $\text{teacher}(0) \wedge \text{student}(1) \wedge \dots \wedge \text{student}(30)$ ,

O:  $\text{euro}(1) \wedge \dots \wedge \text{euro}(20) \wedge \text{asia}(21) \wedge \dots \wedge \text{asia}(27)$   
 $\wedge \text{usa}(28) \wedge \dots \wedge \text{usa}(30)$

First, the ground and irredundant DNF formula

$\neg H1 \vee \neg H2 \vee \neg H3$  is derived from  $B \wedge \neg O$  where

$H1 = (\neg B \vee \text{euro}(1)) \wedge \dots \wedge (\neg B \vee \text{euro}(20))$

$H2 = (\neg B \vee \text{asia}(21)) \wedge \dots \wedge (\neg B \vee \text{asia}(27))$

$H3 = (\neg B \vee \text{usa}(28)) \wedge \dots \wedge (\neg B \vee \text{usa}(30))$ .

# Example

Next,  $O$  is partitioned into  $O = O1 \wedge O2 \wedge O3$  where

$$O1 = \{\text{euro}(1), \dots, \text{euro}(20)\}, \quad O2 = \{\text{asia}(21), \dots, \text{asia}(27)\}, \\ O3 = \{\text{usa}(28), \dots, \text{usa}(30)\}.$$

Then,  $\text{lgs}(H) = \text{lgs}(H1) \wedge \text{lgs}(H2) \wedge \text{lgs}(H3)$  where

$$\text{lgs}(H1) = \neg \text{teacher}(0) \vee \neg \text{student}(x) \vee \text{euro}(x),$$

$$\text{lgs}(H2) = \neg \text{teacher}(0) \vee \neg \text{student}(x) \vee \text{asia}(x),$$

$$\text{lgs}(H3) = \neg \text{teacher}(0) \vee \neg \text{student}(x) \vee \text{usa}(x).$$

As  $O$  is asynchronous,  $\text{gsi}(\text{lgs}(H1), \dots, \text{lgs}(Hn))$  becomes

$$\text{lgs}(H1) \vee \text{lgs}(H2) \vee \text{lgs}(H3).$$

Finally,  $\text{teacher}(0)$  is isolated in each  $\text{lgs}(Hi)$ ,

so removing it from each  $\text{lgs}(Hi)$ , and get  $\text{lgs}^*(Hi)$ .

# Example

As a result,  $H^\wedge = \text{Igs}^*(H1) \wedge \dots \wedge \text{Igs}^*(Hn)$  becomes

$\text{euro}(x) \leftarrow \text{student}(x)$

$\wedge \text{asia}(x) \leftarrow \text{student}(x)$

$\wedge \text{usa}(x) \leftarrow \text{student}(x),$

and  $H^\vee = \text{Igs}^*(H1) \vee \dots \vee \text{Igs}^*(Hn)$  becomes

$\text{euro}(x) \vee \text{asia}(x) \vee \text{usa}(x) \leftarrow \text{student}(x).$

Thus,  $H^\wedge$  and  $H^\vee$  becomes two solutions of brave induction.

# Discussion

## Relation to Learning from Satisfiability (LFS)

- A hypothesis  $H$  covers  $O$  under  $B$  in LFS if  $B \wedge H$  has a model satisfying  $O$  (De Raedt and Dehaspe, 1997).
- If  $H$  covers  $O$  under  $B$  in brave induction,  $H$  covers  $O$  under  $B$  in LFS. The converse implication does not hold in general.
- **LFS does not require the minimality of models**, and any  $H$  which is consistent with  $B \wedge O$  becomes a solution. (e.g.,  $B = \{p(a)\}$ ,  $O = \{q(a)\}$ ,  $H = \{r(b)\}$ .)
- LFS generally produces many useless hypotheses, and brave induction reduces hypotheses space.

# Discussion

## Relation to Confirmatory Induction

- A hypothesis  $H$  covers  $O$  under  $B$  in **confirmatory induction** (or **descriptive induction**) if  $\text{Comp}(B \wedge O) \models H$  where **Comp** is predicate completion.
- There is no stronger/weaker relation between confirmatory induction and brave induction.
- Confirmatory induction does not explain why particular individuals are observed under  $B$ , and the aim is to learn relations between concepts.

# Discussion

## Relation to CF-Induction

- **CF-induction** (Inoue, 2004) applies Muggleton's **inverse entailment** to full clausal theories.
- CF-induction is cautious induction and is stronger than brave induction.

# Discussion

## Handling Negative Observations

- Given a negative observation  $N$ , it is requested that  $B \wedge H \not\models N$ .
- Given a positive observation  $P$  and a negative one  $N$ ,  $H$  is a solution of brave induction if  $B \wedge H$  has a minimal model  $M$  such that  $M \models P$  and  $M \not\models N$ .
- By putting  $O = P \wedge \neg N$ , negative observations are handled within the framework of this paper.

# Discussion

## Computational Complexity

- Given a ground theory  $B$  and a ground observation  $O$ , deciding the existence of solutions in brave induction is **NP-complete**.  
(This is also the case for cautious induction.)
- Identifying whether a propositional theory  $H$  is a solution of brave induction is  **$\Sigma_2^P$ -complete**.  
In cautious induction, the task is **coNP-complete**.
- Brave induction appears more expensive than cautious induction for identifying solutions.

# Conclusion

- Brave induction is **weaker** than explanatory (or cautious) induction, and **stronger** than learning from satisfiability. It is useful for learning **indefinite or incomplete** theories.
- Brave induction is used for automated negotiation in **multiagent systems** for building proposals [Sakama, DALT-08].
- A candidate of practical application is **system biology** which would have indefinite or incomplete information in the background knowledge and observations.
